15. AND/OR Graphs :

directed graph / digraph &amp;

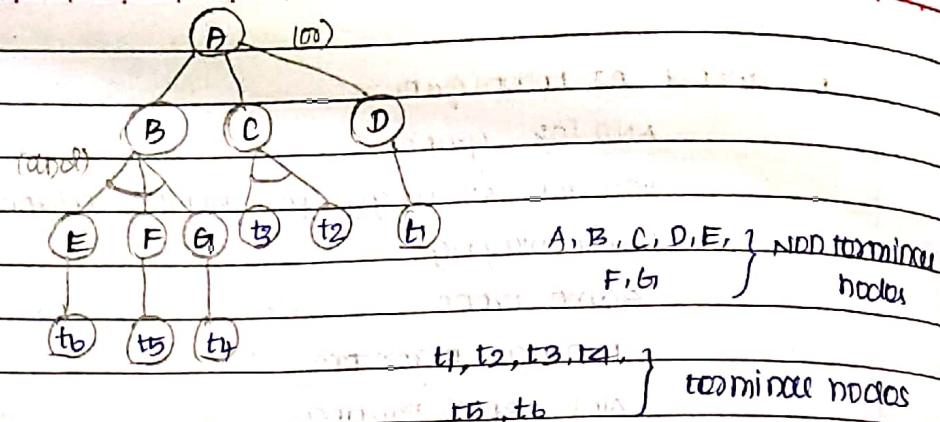

↳ graphical model

for real world AI problems.

20. Example:

and will be indicated  
using arc )25. AND/OR graph is a combination / mixture of all edges are  
of OR edges and AND edges

30

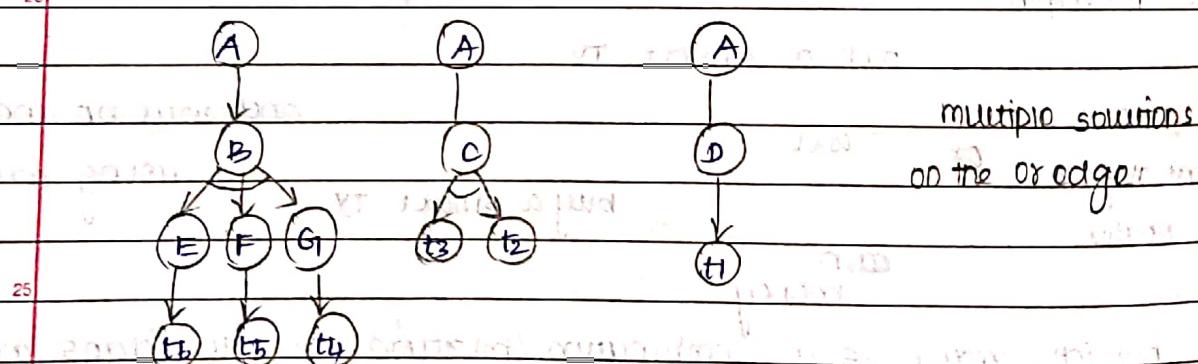

28/03/2023  
⇒ All terminal nodes are solvable nodes  
⇒ All non-terminal nodes are looking for a solution.

unsolved nodes are the non-terminal nodes, present at leaf node they cannot be solved.

solution graph of an AND/OR graph:

Extraction of an AND/OR graph

(subgraph of an AND/OR graph)

An AND/OR graph models a real world scenario using nodes and edges like a traditional graph. However, the edges can be an AND edge or OR edge depending on the real world scenario.

The nodes of the graph indicates events of the real world.

A solution graph is a subgraph or partial graph of the AND/OR graph in which all the terminal nodes are solved nodes. / solvable nodes

The rest of the nodes are called as non-terminal nodes.

Characteristics of AND/OR graph:

(1) Terminal nodes are solved nodes

(2) If the child nodes of any given node are AND nodes then that node is solved with when all those AND nodes are solved.

(3) If the child nodes of any given node are OR nodes, then that node is solved if any one of the OR nodes are solved.

(4) A solution graph is a part of the AND/OR graph all of whose nodes are solved and in which no node including

the start node has more than one edge to an OR node.

(X) (X) (X)

depth first search for extracting solution graph of an AND/OR graph :-

PROCEDURE DFS AND/OR :

Begin

1. PUT into OPEN list an unsolved graph consisting only of the start node.

2. LOOP : If OPEN = EMPTY then EXIT(FAIL)

3. P = FIRST(OPEN) /\* Fetch the first element (unsolved graph)

from the OPEN list \*/

4. If solved (P) then EXIT(SUCCESS)

\* If P is a solved graph, the search has succeeded  
and P is the solution \*/

5. REMOVE (P, OPEN)

6. Expand P, Evaluate all the newly generated  
unsolved graphs and put any unsolved graphs whose  
start nodes are not unsolved at the head of OPEN list (top  
of stack)

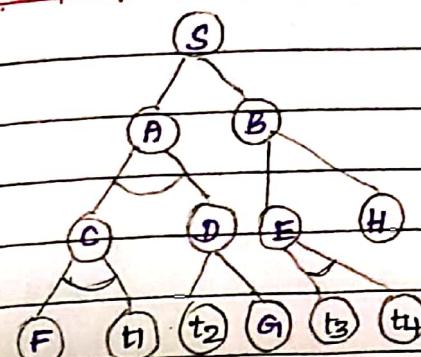

7. goto LOOP

END DFS AND/OR

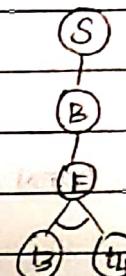

The following AND/OR graph models a real world problem.

Trace DFS to obtain a solution graph to solve

the real world problem. Observe that a AND/OR graph  
includes nodes which are not solvable due to  
uncertainty.

## Game Playing :

Game Trees :

History of AI

→ Game playing in AI

CHESS / Chinese checkers

Game Tree is a data structure which is a tree, consisting of all possible moves of the game which allows the method to move from one state of the game to the next state.

A game tree comprises the following :-

(i) INITIAL STATE / INITIAL STATE :-

This is the initial board position of the game.

(ii) SUCCESSOR FUNCTION :-

This defines the legal moves of the game by the players

(iii) TERMINAL STATE :-

This is the board position when the game gets over. (WIN / LOSS / DRAW)

(iv) UTILITY FUNCTION / PAYOFF FUNCTION :-

This defines a numeric value for the outcome of the game. Utilities of the terminal nodes are used to determine the utilities of other nodes.

Next we will discuss

SEARCH STRATEGIES :-

MINIMAX ALGORITHM

MINIMAX ALGORITHM WITH ALPHA-BETA PRUNING

5 6 7

8 9 10

31/03/2023

Example:

## game of Grundy :

two players have a in front a single pile of coins  
the first player divide the original pile into 2 piles of unequal coins. the piles must be unequal.

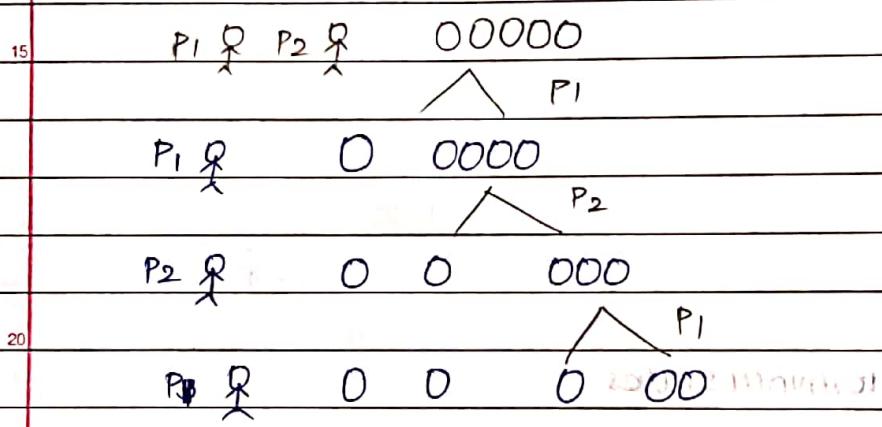

Each player alternately divides any single pile  
when it is his/her turn to play.

the game proceeds until every pile has one or two coins  
at which point continuation is not possible

whichever player cannot continue loses the game.

the winner gets all the coins.

Example : simple example with pile of 5 coins

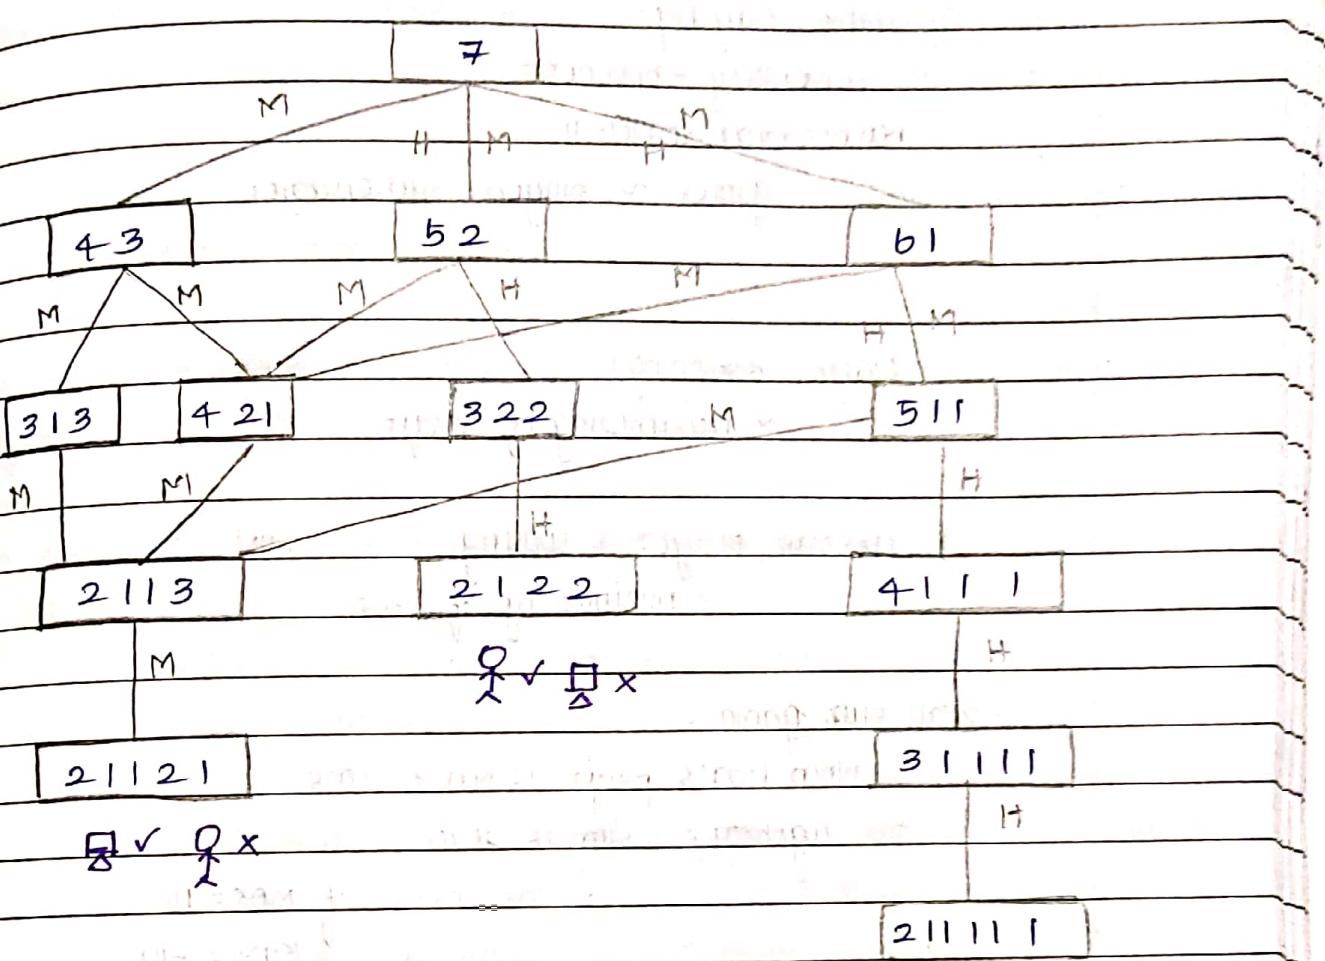

P2 cannot further play.

P1 wins the game

(X) Game Tree cannot have  
duplicate nodes (X)

operation research (OR)

MINIMAX STRATEGY:

In this strategy the two players MAX and MIN are involved where MAX always moves first (opening player)

The minimax strategy has the following elements:

So: Initial state which specifies how the game is setup and how start.

PLAYER(S): defines which player has the move in a state.

ACTION(S): Returns the set of legal moves in a state

RESULT(s,a): the transition model which defines the result of a move.

TERMINALTEST(s): A terminal test which is true when the game is over and false otherwise. states where the game has end it are called terminal states

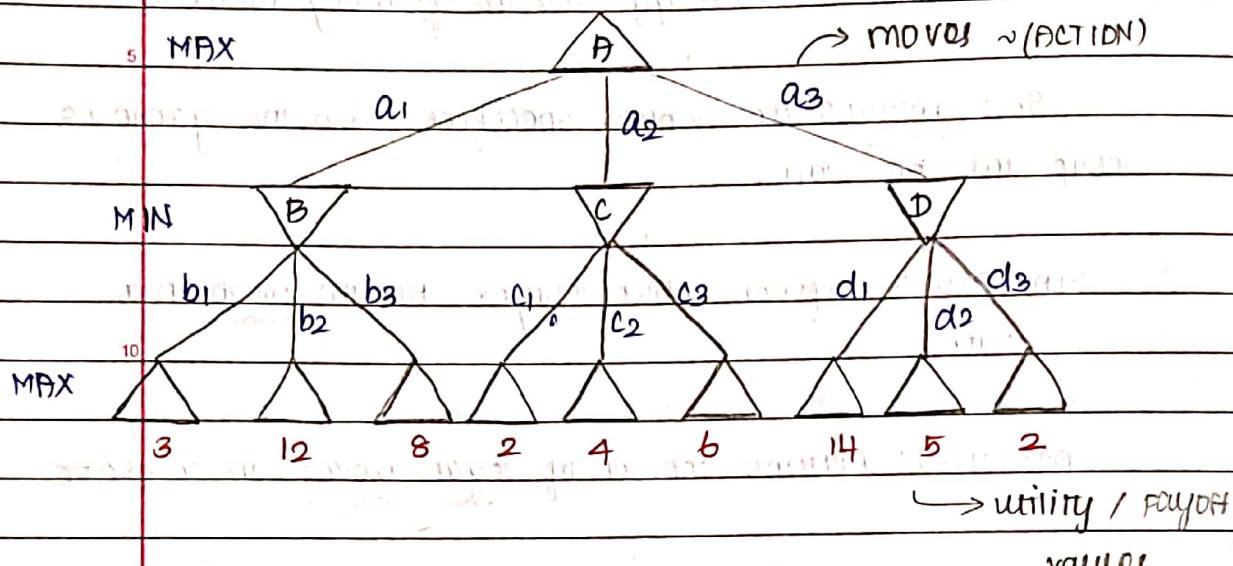

UTILITY(s,p): A utility function (also called objective function / payoff function) defines the final numeric value for a game that ends in a terminal state s, for a player

NOTE:

The initial state, action function ACTION(s), result function RESULT(s,a)

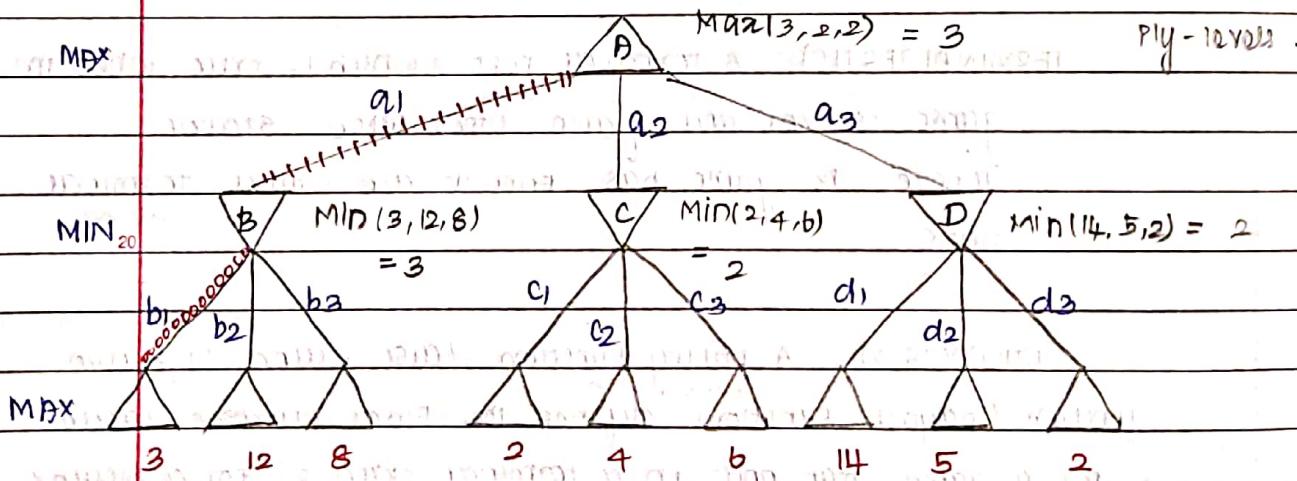

defines a game tree for the two person sum game. Thus, the game tree has game states as the nodes and moves are the edges

The following is an example of a game tree with two players MAX and MIN, playing a zero sum game.

03/04/2023 Minimax strategy :

2-ply game tree

The Minimax strategy is controlled by the following equation:

$$\text{MINIMAX}(S) = \begin{cases} \text{UTILITY}(S) & \text{IF TERMINAL TEST}(S) \text{ IS TRUE} \\ \max(\text{MINIMAX}(\text{RESULT}(S, A))) & \text{IF PLAYER}(S) \text{ IS MAX} \\ \min(\text{MINIMAX}(\text{RESULT}(S, A))) & \text{IF PLAYER}(S) \text{ IS MIN} \end{cases}$$

ACTION(S)

ACTION(S)

function MINIMAX-DECISION (state) returns an action  
 return  $\arg \max_{a \in \text{ACTIONS}} \text{MIN-VALUE}(\text{RESULT}(s, a))$

function MAX-VALUE (state) returns a utility value  
 if TERMINAL-TEST (state) then return UTILITY (state)

$v \leftarrow -\infty$

for each  $a$  in ACTIONS (state) do

$v \leftarrow \max(v, \text{MIN-VALUE}(\text{RESULT}(s, a)))$

return  $v$ .

function MIN-VALUE (state) returns a utility value

if TERMINAL-TEST (state) then return UTILITY (state)

$v \leftarrow \infty$

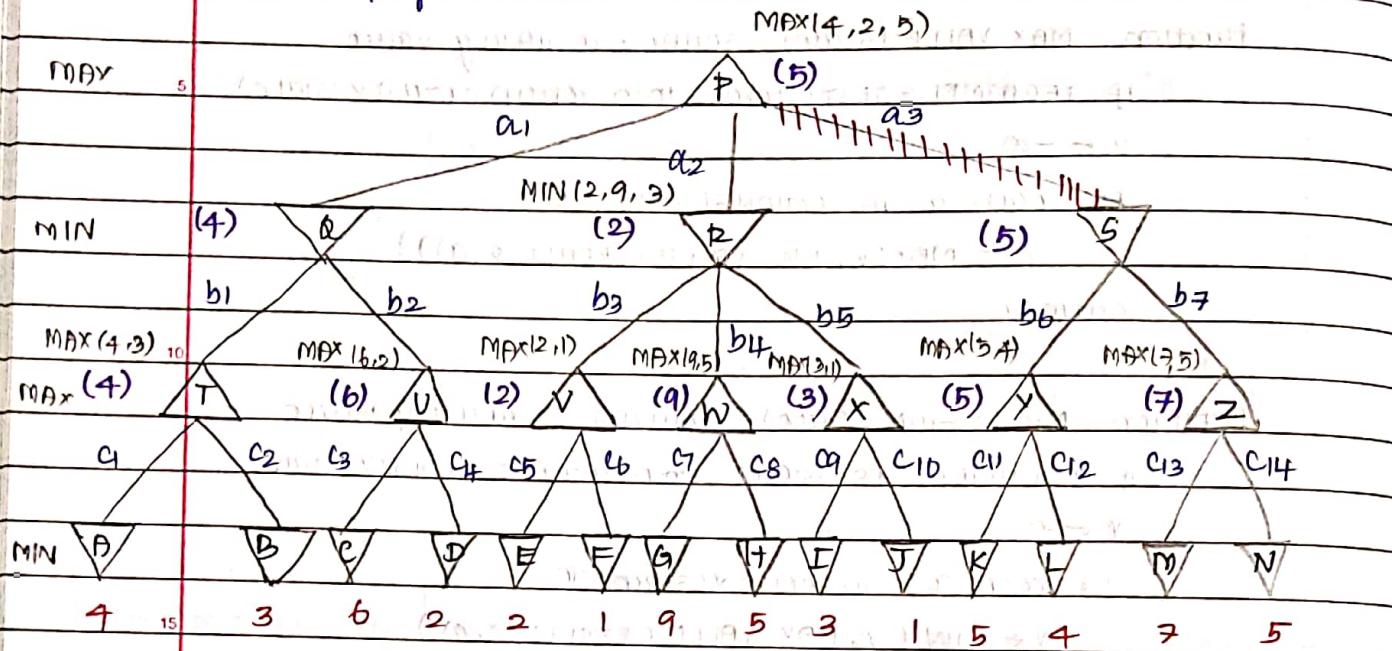

for each  $a$  in ACTIONS (state) do

$v \leftarrow \min(v, \text{MAX-VALUE}(\text{RESULT}(s, a)))$

return  $v$ .

An algorithm for calculating minimax decisions. It returns no action corresponding to the best possible move, that is, the move that leads to the outcome with the best utility, under the assumption that the opponent plays to minimize utility. The functions MAX-VALUE and MIN-VALUE go through the whole game tree, all the way to the leaves to determine the backed-up values of a state. The notation  $\arg \max_a f(a)$  computes the element  $a$  of set  $S$  that has the maximum value of  $f(a)$ .

For the following game tree (3 ply) trace MINIMAX strategy and obtain the strategy played by MAX to maximize his profit.

Strategy played by MAX is  $a_3$  with

minimum profit of 5

If you want to draw the game tree for chess game parameters are :-

The average no of branches = 35

In a every second of game, the average no of

moves of player = 50 [ For two players - 100 moves ]

No. of nodes  $\geq 35^{100}$  nodes

approximately  $10^{10}$  terminal nodes

In general a game tree can be humongous.

Considering two persons sum game, the minimax strategy explores the complete game tree before it finds the strategy for MAX.

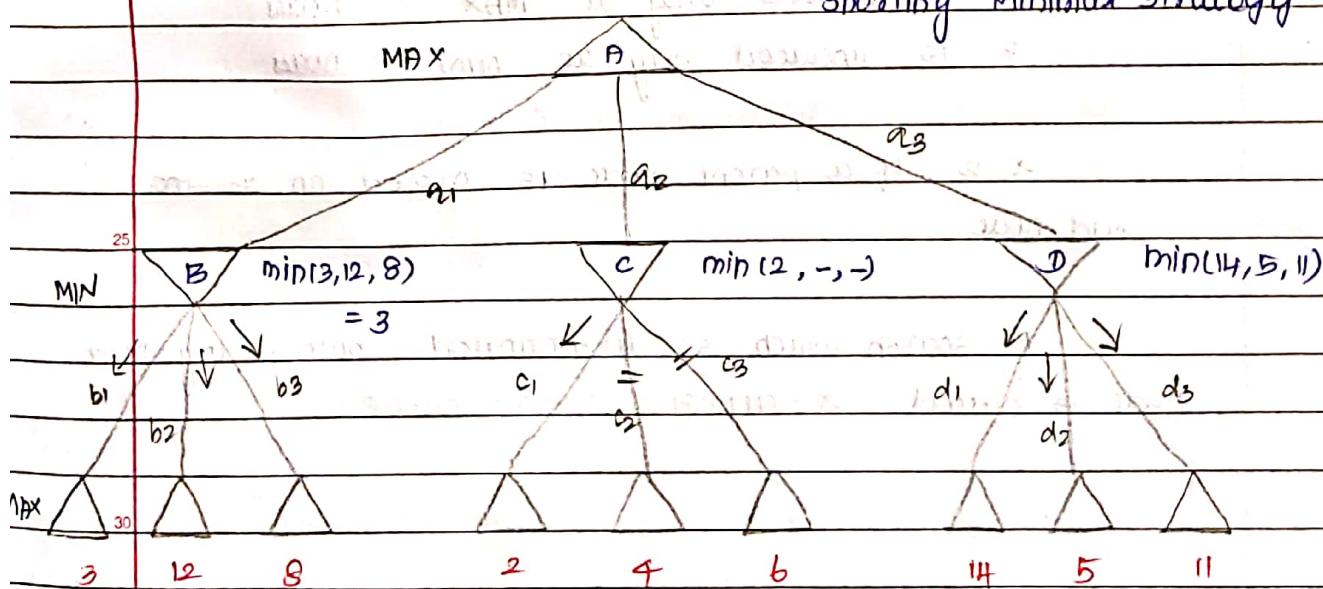

Time constraint is very large.

The minimax strategy has the disadvantage that as it goes through all the nodes, and its an time consuming task.

Example :-

max(3, -5)

shorting minimax strategy

discard is what is called as pruning

the minimax strategy which incorporates pruning is called alpha-beta pruning.

Alpha and Beta are two parameters which helps the implement the logic behind pruning.

#### WORK RULE FOR ALPHA - BETA PRUNING:

Every node in the minimax tree is assigned with alpha beta value as  $[\alpha, \beta]$  value

Initially, Alpha, Beta  $[\alpha, \beta]$  is assigned as  $[-\infty, \infty]$

Throughout the working, the values of  $\alpha$  and  $\beta$  should be  $\alpha \geq \beta$  (Pruning strategy)

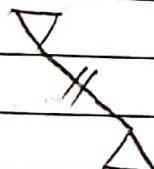

If  $\alpha \geq \beta$  then pruning condition is executed

$\alpha$  is updated only at MAX nodes

$\beta$  is updated only at MIN nodes

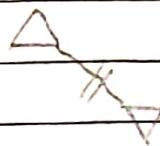

$\alpha, \beta$  of a parent node is passed on to the child node

A search which is discontinued below any MIN node is called  $\alpha$ -cutoff (Alpha-cutoff)

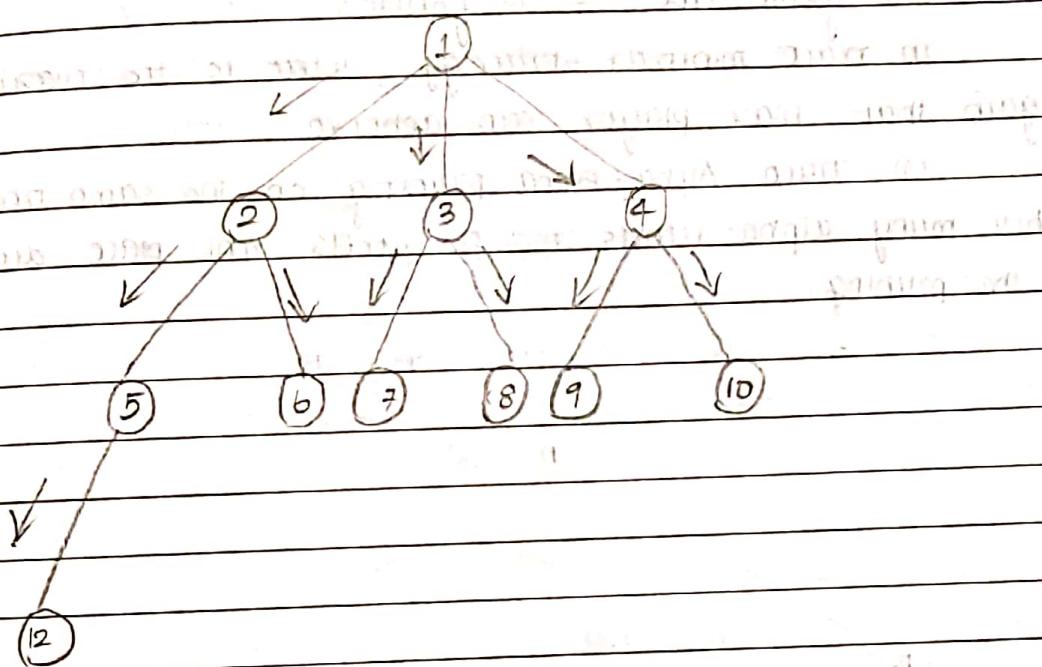

search discontinued below any max node is called

B-CUT OFF (beta cutoff)

Alpha-beta pruning just like minimax strategy adopts depth first search.

10/04/2023

 $\alpha - \beta$  Pruning :: (Problems) $\hookrightarrow \alpha, \beta$ 

Rules :

$$[\alpha, \beta] = [-\infty, \infty]$$

 $\alpha < \beta$  throughout loop

 $\alpha \geq \beta$  pruning condition

$$\alpha \Rightarrow \Delta$$

$$\beta \Rightarrow \nabla$$

 ~~$\Delta$~~   $\Rightarrow$  Alpha - CutOff

 ~~$\nabla$~~   $\Rightarrow$  Beta - CutOff

A Minimax game tree is as follows

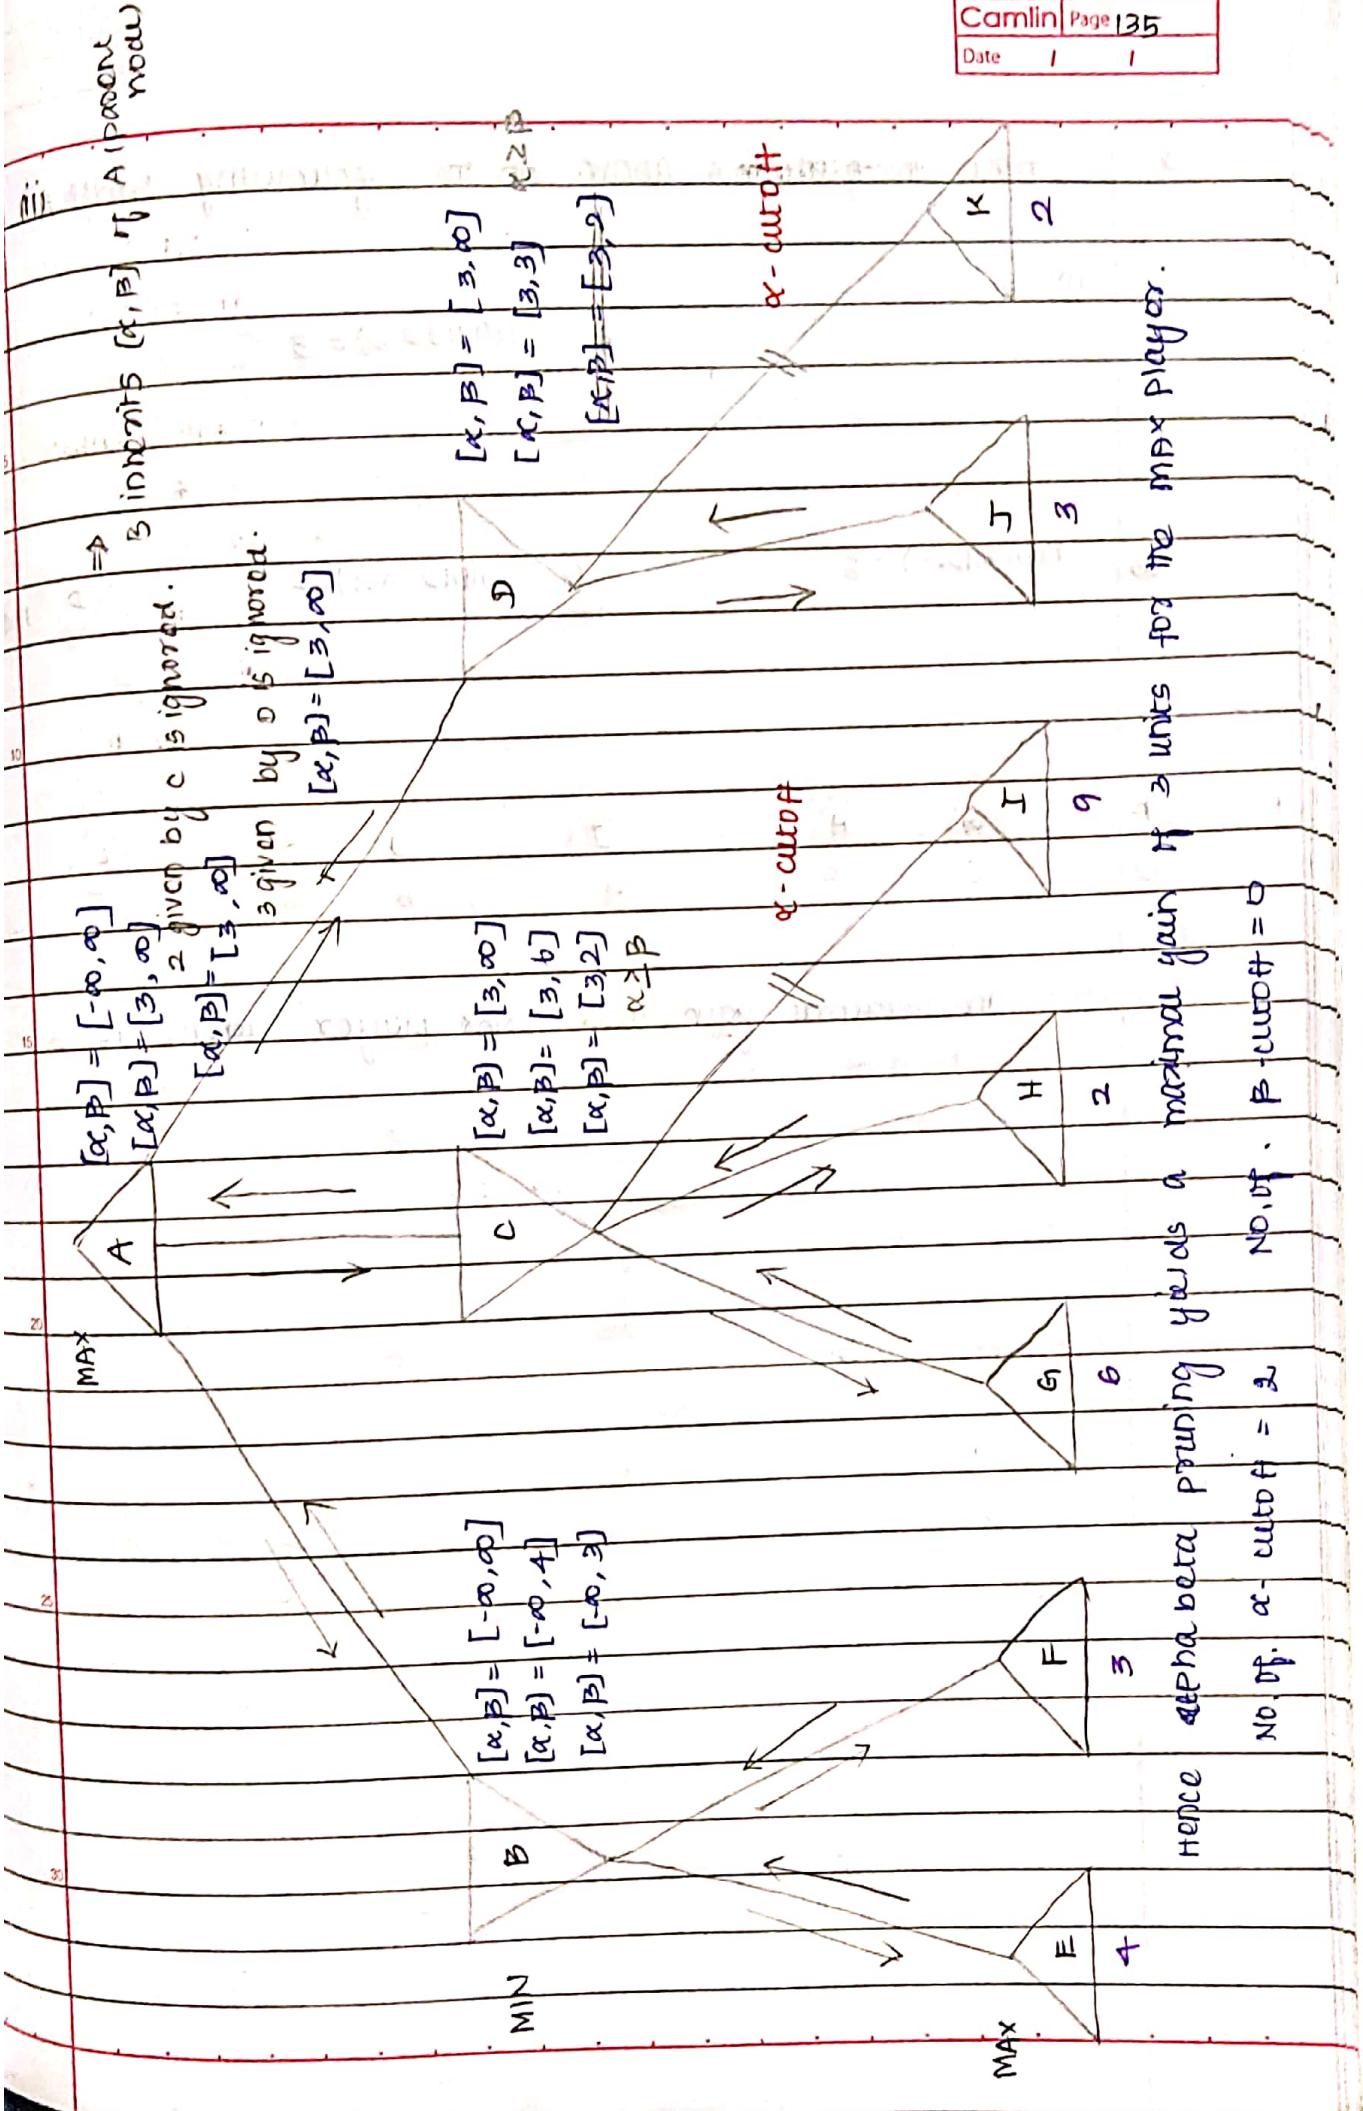

(i) trace minimax strategy, what is the maximum gain that max player can achieve

(ii) trace Alpha-Beta pruning on the same tree, how many alpha-cutoffs and beta-cutoffs took place during the pruning.

(i)

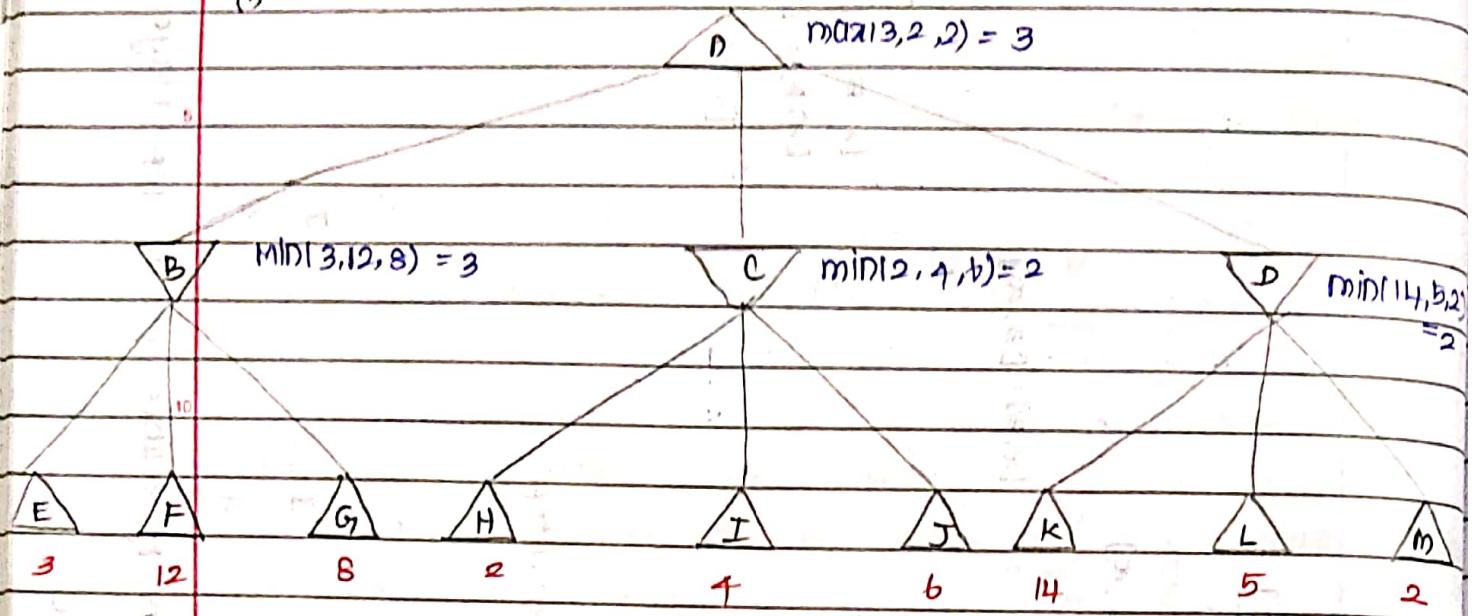

The maximal gain that max player achieves is 3.

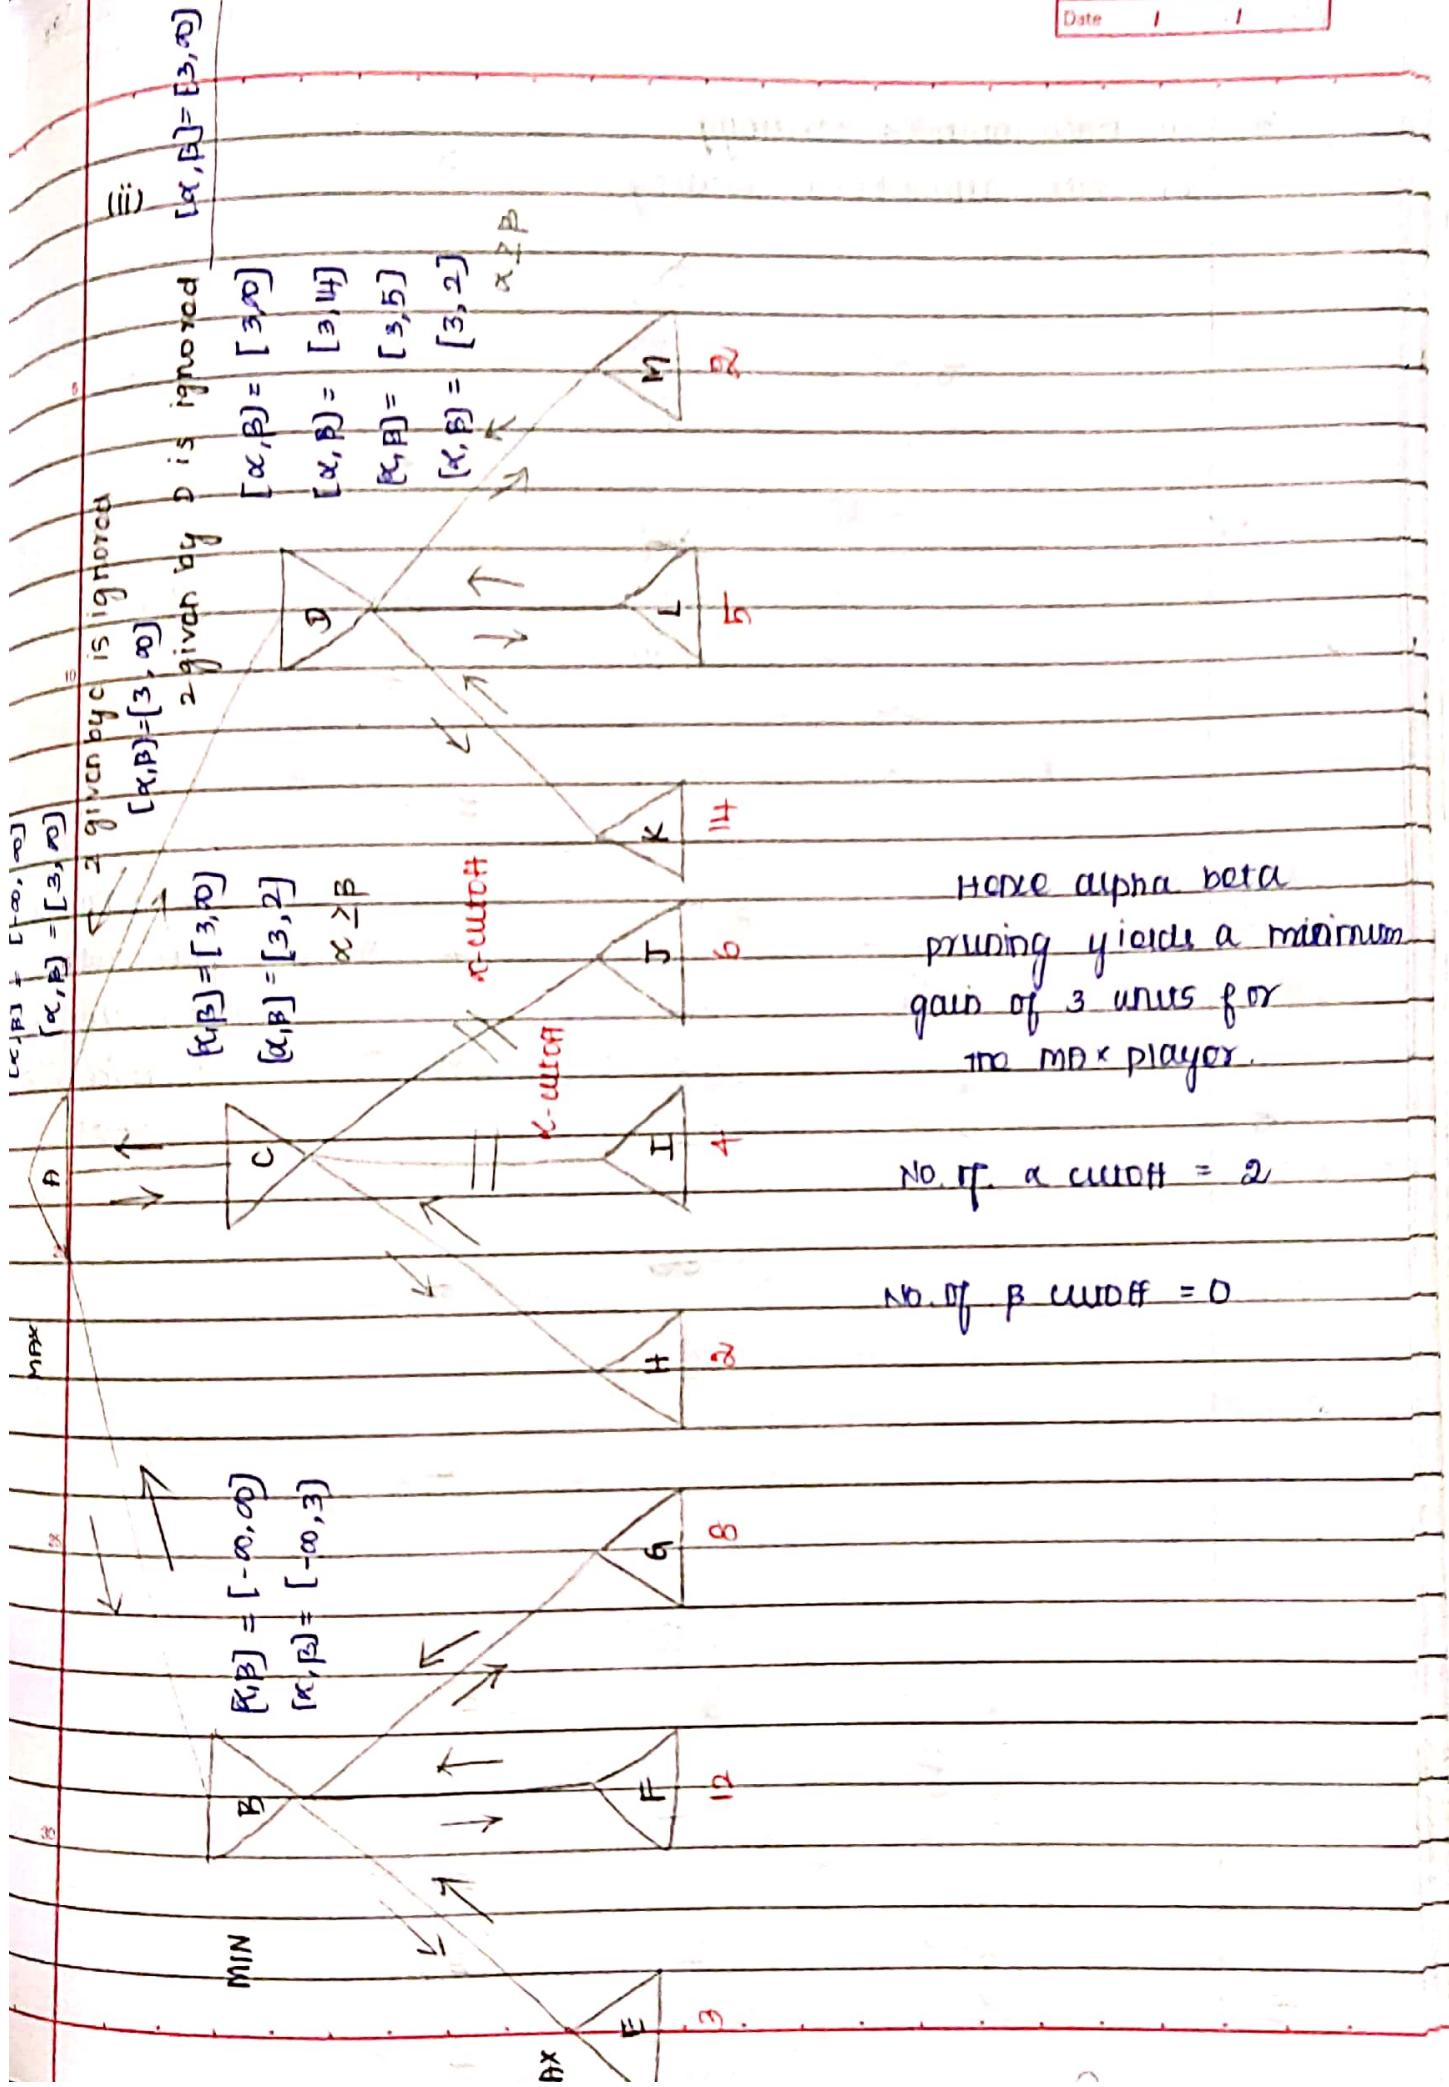

2. solve the questions above on the following MINIMAX tree.

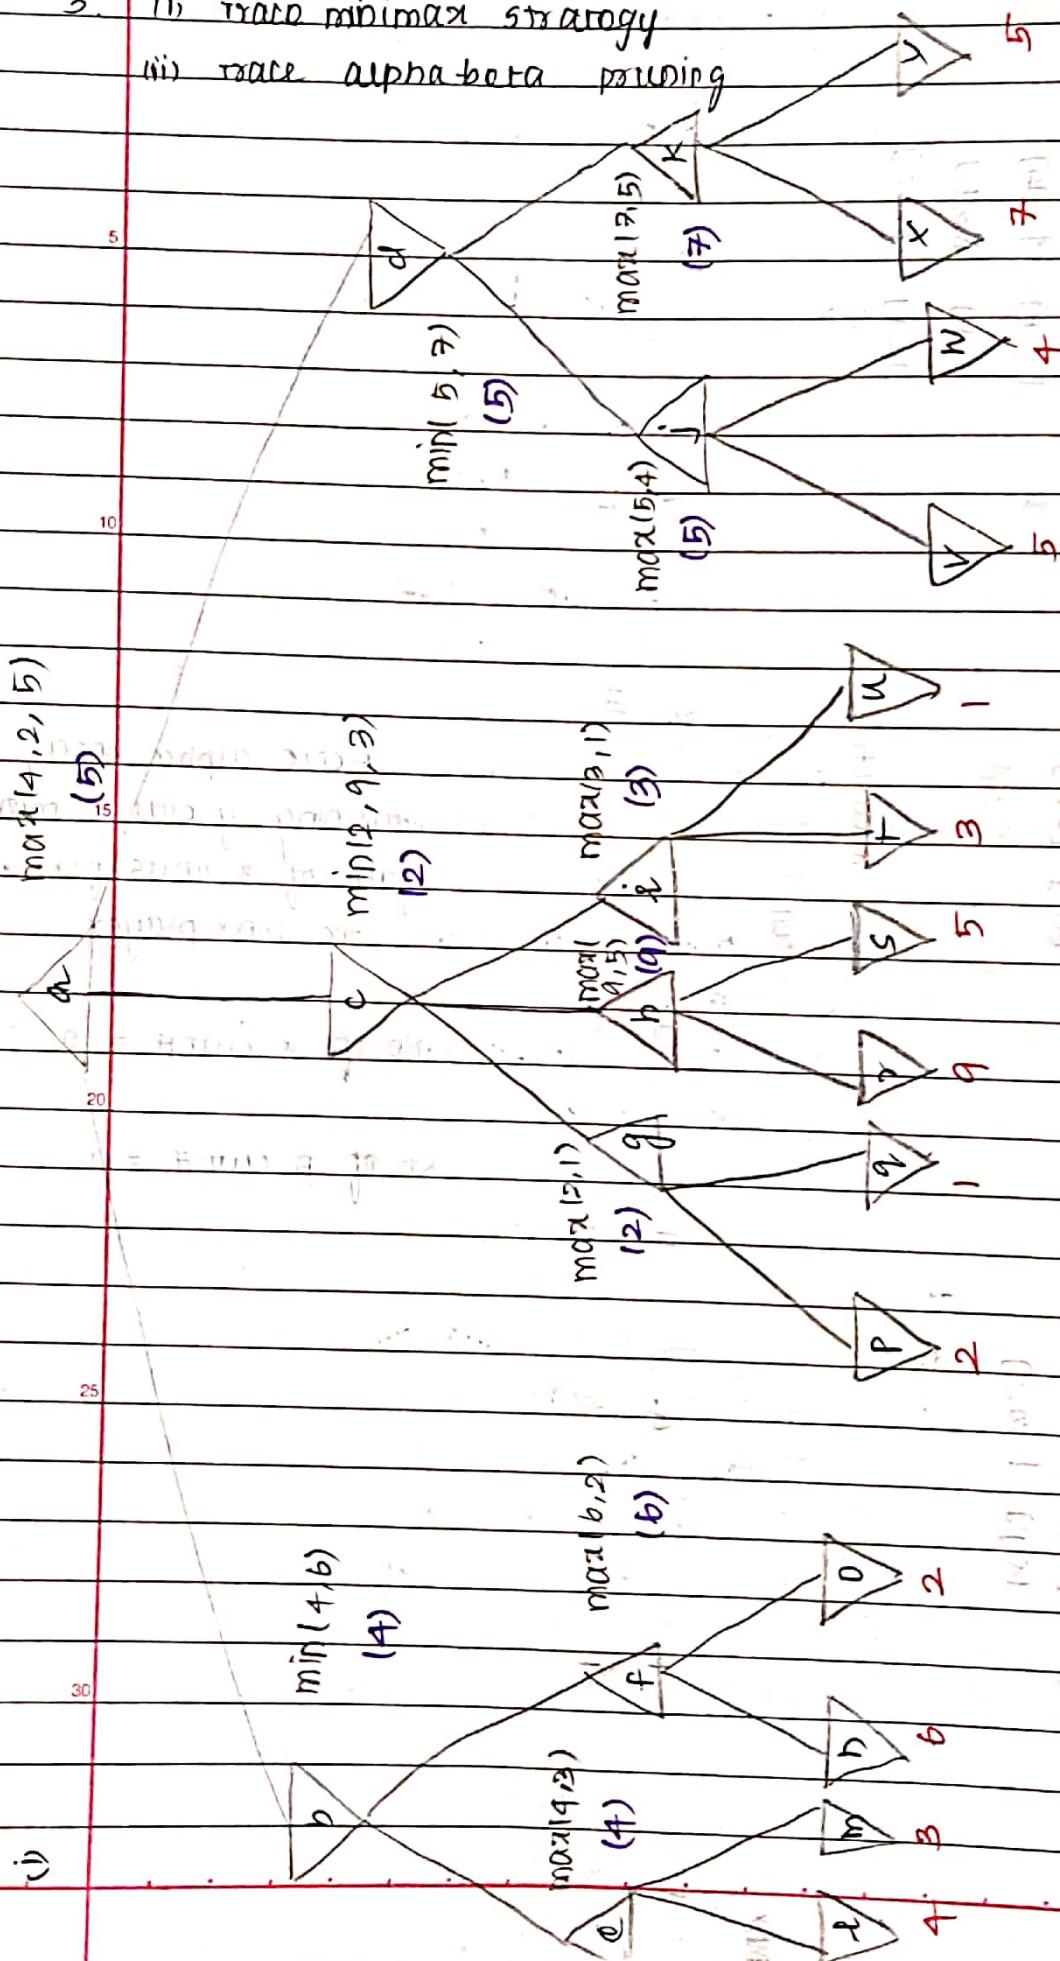

(i)

The maximum gain that MAX player achieves is 3.

3. (i) trace minimax strategy  
 (ii) trace alpha-beta pruning

$$[x_1, p] = [+, \infty] = [4, 5]$$

↗ more ↘

$$\begin{aligned} [K, B] &= [4 \\ &= [7, 5] \end{aligned}$$

$\alpha \geq \beta$

pointing  
toward condition

~~P - cut off~~

A diagram of a triangle with vertices labeled A, B, and C. Vertex A is at the top right, vertex B is at the bottom left, and vertex C is at the bottom right. The interior angle at vertex A is labeled with the Greek letter alpha ( $\alpha$ ). The interior angles at vertices B and C are labeled with question marks (?) indicating they are unknown or to be calculated.

Hence alpha  
beta pruning  
yields maximum  
gain of  
5 units for  
the MAX player

$$[x, p] = [4, 1] = [4, 0]$$

NO. OF  $\alpha$ -CUTS = 2

方針、方針の実現性を検討する

A diagram illustrating the intersection of two lines. One line is labeled 'x' and the other 'y'. The intersection point is marked with a circle and labeled 'G'. Several angles are labeled:  $\alpha$ ,  $\beta$ ,  $\gamma$ ,  $\delta$ ,  $\epsilon$ , and  $\zeta$ . There are also some unlabeled arrows pointing towards the intersection point.

$$\text{NO. OF P. } P \cup T \cap A = 2$$

$$\text{ignored}$$

$x, p_1 = [-\infty, 4]$   
 $\geq P$  pruning condition  
occur at 0

1000

$$[x, \beta] = \begin{bmatrix} -1 \\ 1 \end{bmatrix} = g$$

ground

—  
—

A hand-drawn graph on lined paper illustrating the intersection of a demand curve and a supply curve. The vertical axis is marked with a red '30' at the top. The horizontal axis has several tick marks. A downward-sloping line is labeled 'Demand' with an arrow pointing to it. An upward-sloping line is labeled 'Supply' with an arrow pointing to it. The two lines intersect at a point labeled 'E'.

$$[\alpha, \beta] = [\gamma]$$

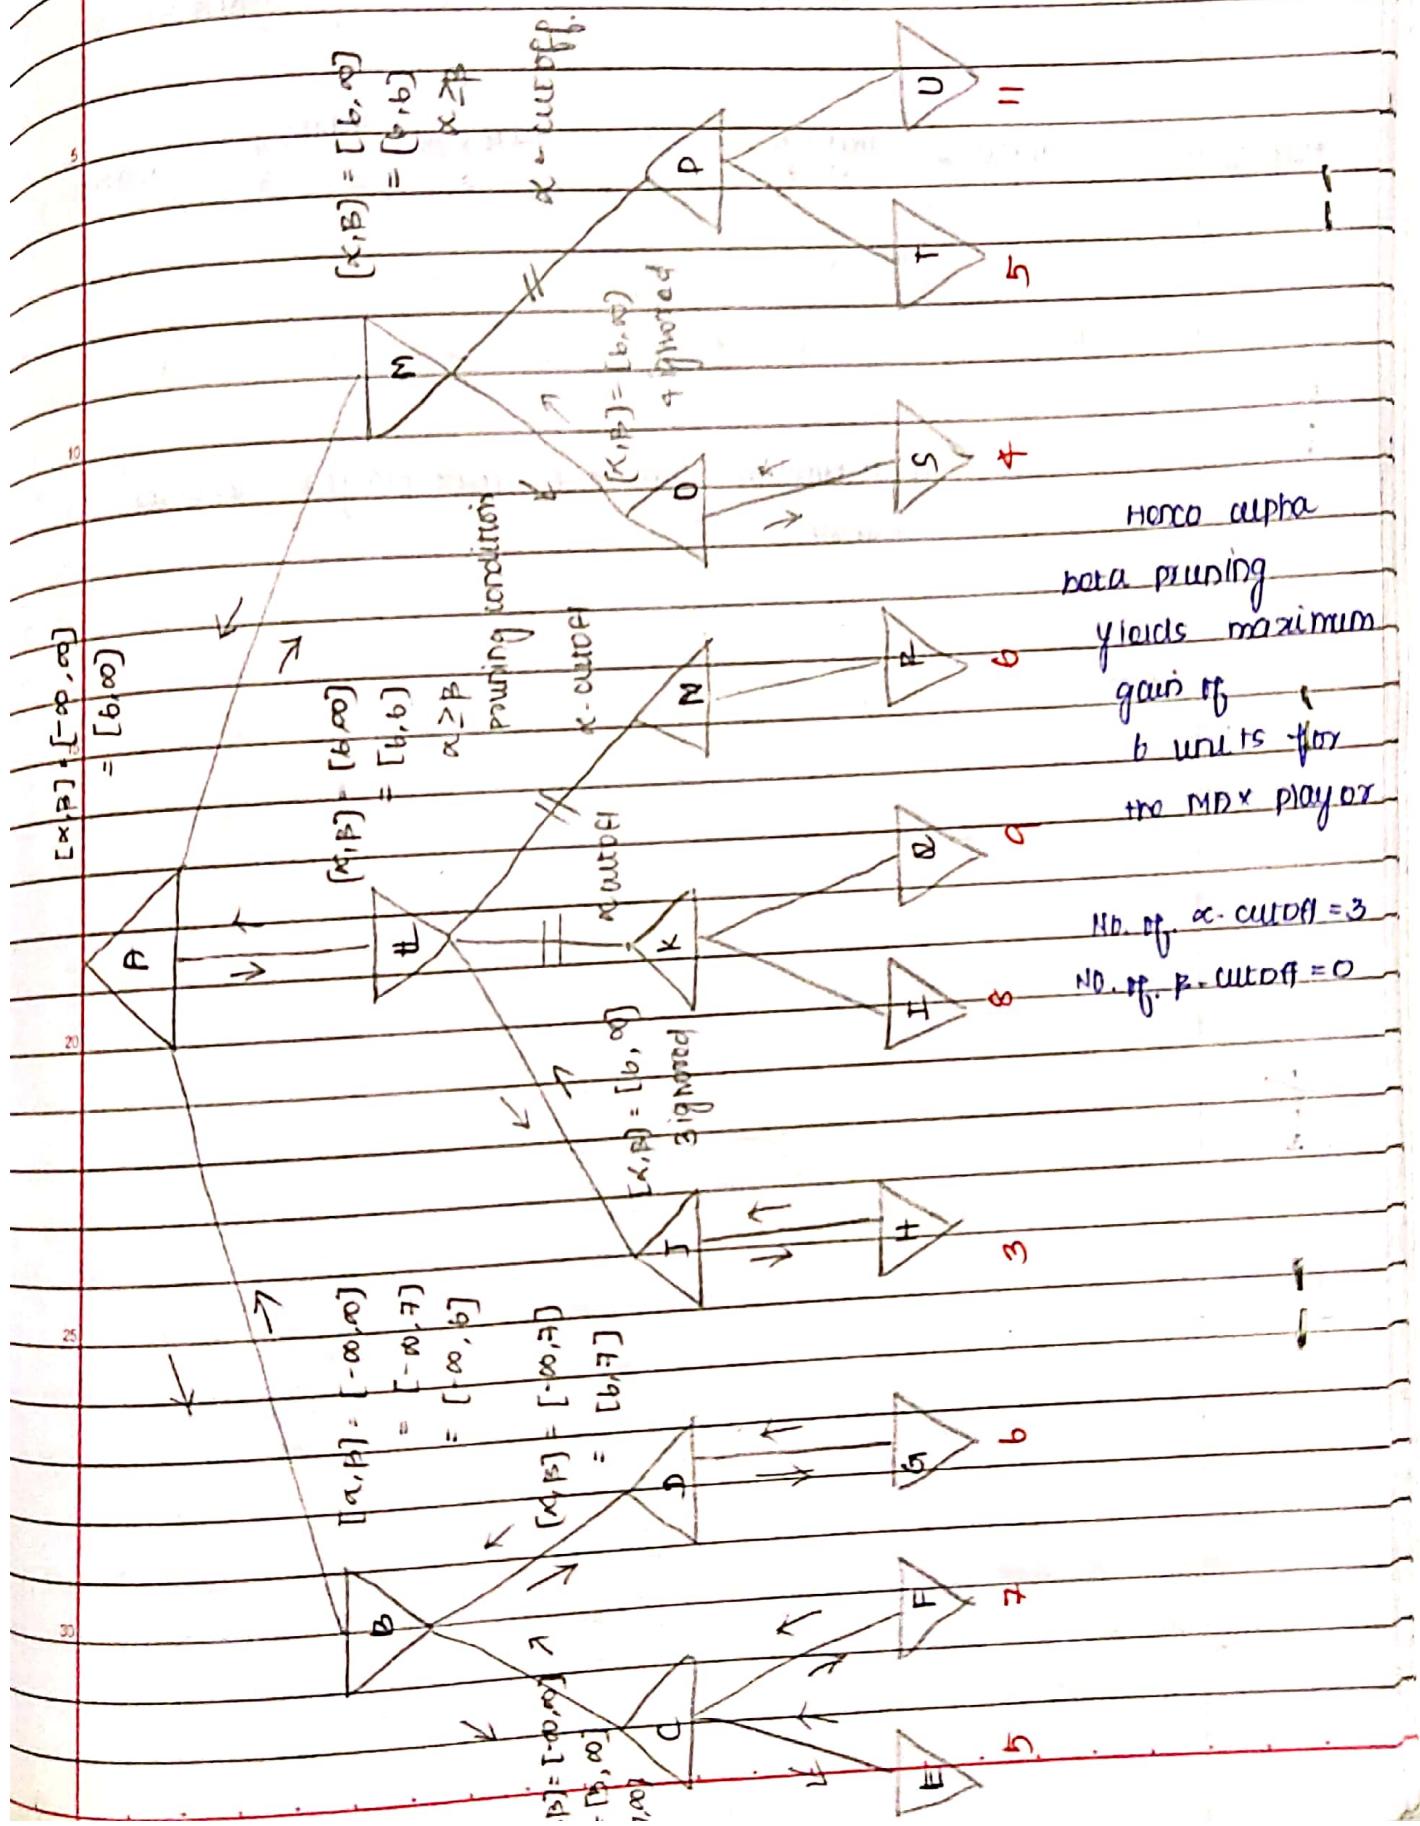

function ALPHA-BETA-SEARCH (state) returns an action  
 $v \leftarrow \text{MAX-VALUE} (\text{state}, -\infty, +\infty)$   
 return the action in ACTIONS(state) with value  $v$

5 function MAX-VALUE (state,  $\alpha, \beta$ ) returns a utility value  
 if TERMINAL-TEST (state) then return UTILITY (state)  
 $v \leftarrow -\infty$   
 for each  $a$  in ACTIONS (state) do  
 $v \leftarrow \text{MAX} (v, \text{MIN-VALUE} (\text{RESULT} (s, a), \alpha, \beta))$   
 if  $v \geq \beta$  then return  $v$   
 $\alpha \leftarrow \text{MAX} (\alpha, v)$   
 return  $v$

function MIN-VALUE (state,  $\alpha, \beta$ ) returns a utility value  
 if TERMINAL-TEST (state) then return UTILITY (state)  
 $v \leftarrow +\infty$   
 for each  $a$  in ACTIONS (state) do  
 $v \leftarrow \text{MIN} (v, \text{MAX-VALUE} (\text{RESULT} (s, a), \alpha, \beta))$   
 if  $v \leq \alpha$  then return  $v$   
 $\beta \leftarrow \text{MIN} (\beta, v)$   
 return  $v$

the alpha-beta search algorithm. Notice that the conditions are the same as the MINIMAX functions, except for the two lines in each of MIN-VALUE and MAX-VALUE that maintains  $\alpha$  and  $\beta$  (and the bookkeeping to pass those parameters along).

Trace alpha beta pruning on the following MINIMAX tree.

## constraint satisfaction problem (CSP):

real world problem

(constraints)

problem is said to be solvable

only if conditions are  
solved  $\Rightarrow$  technically called as  
as solution is  
caused

Advanced AI strategies

theory

values  $\sim$  domains

$\rightarrow$  minimax

conditions  $\sim$  constraints

strategy

Alpha beta

pruning

definition of CSP:

constraint satisfaction  
problem (CSP)

a constraint satisfaction problem (CSP)  
consists of three components  $x$ ,  $D$ , and  $C$ .  $x$  is set  
of variables  $[x_1, x_2, \dots, x_n]$   $D$  is a set of domains  
 $[D_1, D_2, \dots, D_n]$  one per each variable  
(i.e.),  $D_i$  for  $x_i$ .  $C$  is a set of constraints (conditions)

that specify allowable combinations of values.

Each domain  $D_i$  consists of a set of allowable values  
 $(v_1, v_2, \dots, v_k)$  for variable  $x_i$ .

Each constraint  $c_i$  consists of a  
pair  $\langle \text{scope}, \text{rel} \rangle$  where scope  
is a tuple of variables that  
participate in the constraints and  
the rel is the relation that

defines the values that those variables  
can take  $\Omega$ .

solution satisfies all condition

$\rightarrow$  feasible solution.

optimal solution:

most feasible solution  
which satisfies the objective  
function

(Min or Max)

as the case may be)

Example:

If  $x_1$  and  $x_2$  both have domain  $\{A, B\}$  then the constraint saying that the two variables must have different values is

written as

$$\langle (x_1, x_2), x_1 \neq x_2 \rangle$$

An alternate way of writing the constraint can be as follows

$$\langle (x_1, x_2), \{(A, B), (B, A)\} \rangle$$

or  $\langle (x_1, x_2), \{x_1 \neq x_2\} \rangle$

or  $\langle (x_1, x_2), \{x_1 \neq x_2, x_1 \in \{A, B\}, x_2 \in \{A, B\}\} \rangle$

or  $\langle (x_1, x_2), \{x_1 \neq x_2, x_1 \in \{A, B\}, x_2 \in \{A, B\}, x_1 \neq x_2\} \rangle$

or  $\langle (x_1, x_2), \{x_1 \neq x_2, x_1 \in \{A, B\}, x_2 \in \{A, B\}, x_1 \neq x_2, x_1 \neq x_2\} \rangle$

or  $\langle (x_1, x_2), \{x_1 \neq x_2, x_1 \in \{A, B\}, x_2 \in \{A, B\}, x_1 \neq x_2, x_1 \neq x_2, x_1 \neq x_2\} \rangle$

or  $\langle (x_1, x_2), \{x_1 \neq x_2, x_1 \in \{A, B\}, x_2 \in \{A, B\}, x_1 \neq x_2, x_1 \neq x_2, x_1 \neq x_2, x_1 \neq x_2\} \rangle$

or  $\langle (x_1, x_2), \{x_1 \neq x_2, x_1 \in \{A, B\}, x_2 \in \{A, B\}, x_1 \neq x_2, x_1 \neq x_2, x_1 \neq x_2, x_1 \neq x_2, x_1 \neq x_2\} \rangle$

or  $\langle (x_1, x_2), \{x_1 \neq x_2, x_1 \in \{A, B\}, x_2 \in \{A, B\}, x_1 \neq x_2, x_1 \neq x_2\} \rangle$

or  $\langle (x_1, x_2), \{x_1 \neq x_2, x_1 \in \{A, B\}, x_2 \in \{A, B\}, x_1 \neq x_2, x_1 \neq x_2\} \rangle$

or  $\langle (x_1, x_2), \{x_1 \neq x_2, x_1 \in \{A, B\}, x_2 \in \{A, B\}, x_1 \neq x_2, x_1 \neq x_2\} \rangle$

or  $\langle (x_1, x_2), \{x_1 \neq x_2, x_1 \in \{A, B\}, x_2 \in \{A, B\}, x_1 \neq x_2, x_1 \neq x_2\} \rangle$

or  $\langle (x_1, x_2), \{x_1 \neq x_2, x_1 \in \{A, B\}, x_2 \in \{A, B\}, x_1 \neq x_2, x_1 \neq x_2\} \rangle$

or  $\langle (x_1, x_2), \{x_1 \neq x_2, x_1 \in \{A, B\}, x_2 \in \{A, B\}, x_1 \neq x_2, x_1 \neq x_2\} \rangle$

or  $\langle (x_1, x_2), \{x_1 \neq x_2, x_1 \in \{A, B\}, x_2 \in \{A, B\}, x_1 \neq x_2, x_1 \neq x_2\} \rangle$

or  $\langle (x_1, x_2), \{x_1 \neq x_2, x_1 \in \{A, B\}, x_2 \in \{A, B\}, x_1 \neq x_2, x_1 \neq x_2\} \rangle$

or  $\langle (x_1, x_2), \{x_1 \neq x_2, x_1 \in \{A, B\}, x_2 \in \{A, B\}, x_1 \neq x_2, x_1 \neq x_2\} \rangle$

or  $\langle (x_1, x_2), \{x_1 \neq x_2, x_1 \in \{A, B\}, x_2 \in \{A, B\}, x_1 \neq x_2, x_1 \neq x_2\} \rangle$

Technical keywords of a CSP problem:

- To solve a CSP, we need to define a state space and the notion of the solution. Each state in a CSP is defined by an assignment of values to some or all of the variables.

$$(i.e) \{x_1 = v_1, x_2 = v_2, \dots, x_n = v_n\}$$

An assignment that doesn't violate any constraint is called **consistent** or **legal assignment**.

A **complete assignment** is one in which every variable is assigned and a **solution** to a CSP is a consistent, complete assignment.

A **partial assignment** is one that assigns values to only some of the variables. → non-deterministic polynomial

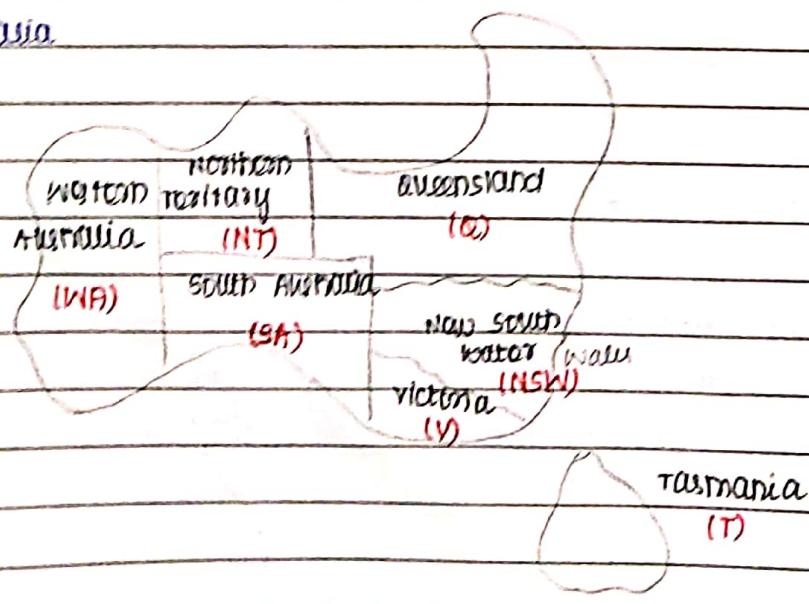

→ NP

CASE STUDY: MAP COLOURING: (NP complete problem)

"exponential time complexity"

No. of colours - chromatic number

Let us consider the principle states and the territories of Australia

The objective is to colour the map with three colours (Red, Blue, Green)

Human approach:

Start by WA -> Red or NT -> Blue or SA -> Green etc.

(Assume WA = Red) then NT = Blue & V = Red or V = Green

AI approach:

AI regards this problem as a CSP, where the constraint is

WA

(i) the no of colours given (Red, Blue, Green)

(ii) NO two adjacent states or territories can have the same colour.

We define the CSP problem as follows

variables  $X$  (states & territory) = {WA, NT, SA, Q, NSW, V, T}

domain  $D$  (colour) = {Red (R), Blue (B), Green (G)}

constraints  $C = \{ \begin{array}{l} WA \neq NT, WA \neq SA, NT \neq SA, NT \neq Q, \\ SA \neq Q, SA \neq NSW, SA \neq V \\ NSW \neq V, Q \neq NSW \end{array} \}$

solution is to be obtained by solving the CSP problem is a complete and consistent assignment of the values Red, Blue, Green to the 7 variables.

A possible solution is

{WA = R, NT = B, SA = G, Q = R, NSW = B, V = P, T = G}

→ NP deterministic

Map colouring :: NP complete Problem.

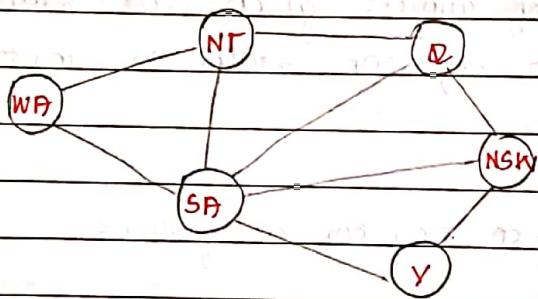

"exponential time complexity"

I/P  
state space model ↗

depth first search

In the next phase the map has to be transformed into a state space model which is a graph (undirected graph) such a graph is called a **constraint graph**.

The constraint graph has the variables ( $x$ ) as the **Nodes**. And the adjacency as its **Edges**.

In the next stage we invoke depth first search on the constraint graph and trace the order in which the nodes are visited. → DFS - systematic search.
